

- 1) Open the workspace “SISO\_wrk” in ADS. The following window shown in Figure 1 is displayed.

- 2) Possible modifications in the design:
  - a. The size of the Chu's antenna (depends on the center frequency)
  - b. The measurement bandwidth in the S-parameters block shown in Figure 1
  - c. Order of LC ladder (Remember to introduce extra variable names if you increase the length of the LC ladder. For optimizing the new variables, you need to add them manually using the "Simulation Variables Setup" option under the "Simulate" tab.)
  - d. Optimization goals- The values for OptimGoal1 are obtained using the `quantize_tx_coeff()` function in MATLAB file "Main\_SISO\_achievable\_rate.m". The number of quantization levels for the transmission coefficient can be increased by changing the variable `sub_groups_num` in the MATLAB code. The upper and lower frequency range can be changed depending on the choice of the bandwidth variable in MATLAB code
- 3) After simulating the design, the following window shown in Figure 2 is displayed. By clicking on the plot of `Eq_Tx`, export the plot in the tab-delimited ASCII format. This format is then read in MATLAB file "Main\_SISO\_achievable\_rate.m" using `tdfread()` function and used for generating plots for SNR, transmission coefficient, and achievable rate.

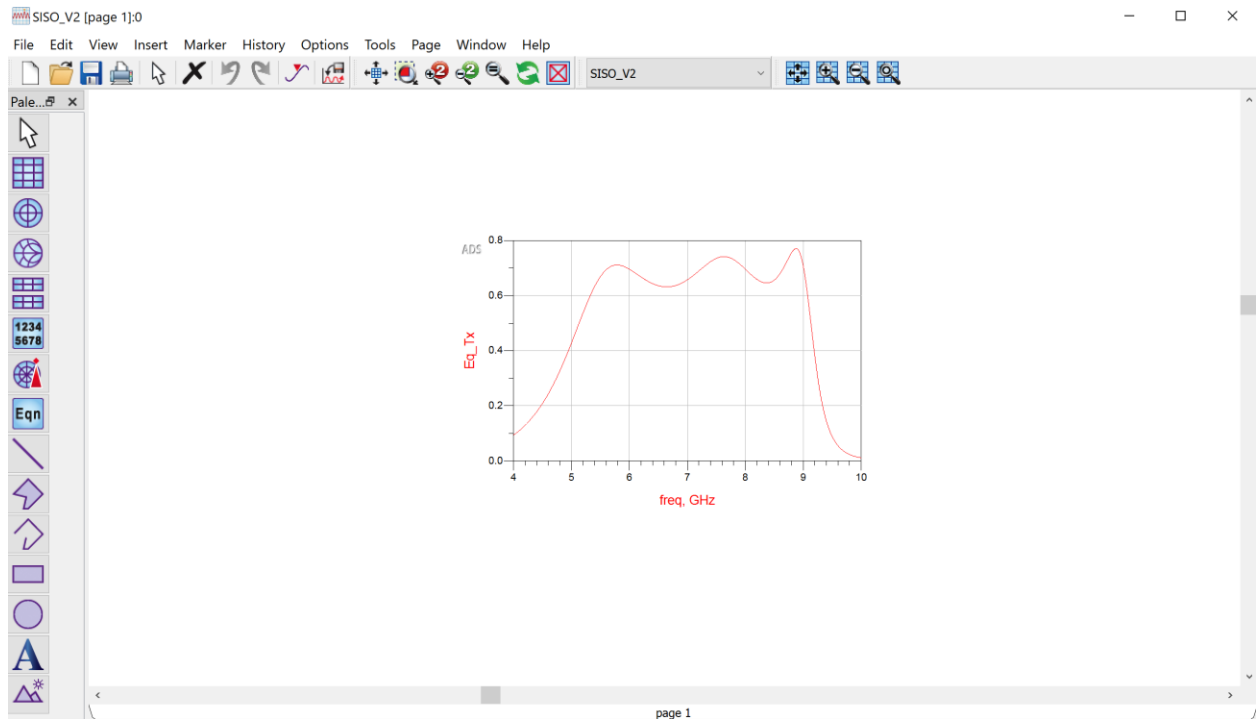

Figure 2: Window after the simulation is done. The plot is exported in the tab-delimited ASCII format saved as a .txt file and can be read by MATLAB script.
